Contents

- Overview
- Ventilation Strategy
- Displacement Ventilation
- Chilled Ceiling
- Lighting Control

Overview

- Building services systems being controlled
 - **HVAC** (heating, ventilation & air-conditioning)
 - Fire services
 - Plumbing & drainage
 - Electrical installations
 - Lighting
 - Lifts & escalators
 - Security & communication
 - Special systems e.g. medical gas

Examples of control systems and devices in buildings

[Source: E Source]

Overview

- Examples of low-energy air conditioning and lighting control*
 - 1. Mixed mode or hybrid ventilation
 - 2. Displacement ventilation
 - 3. Chilled ceiling
 - 4. Lighting control

[* See also: Levermore, G. J., 2000. *Building Energy Management Systems: Application to Low-energy HVAC and Natural Ventilation Control*, 2nd ed., Chp. 12, E & FN Spon, London & New York.]

Ventilation Strategy

- A primary goal when designing high performance energy efficient buildings is to <u>eliminate or reduce</u> the need for cooling or heating equipment
- This may not be possible in severe cold or hot climates, but should still be a key design aim
- Ventilation design strategy for HVAC:
 - Passive design approach, before mechanical systems are applied

Ventilation Strategy

- Key factors affecting natural ventilation:
 - Depth of space related to ventilation openings
 - Ceiling height
 - Thermal mass exposed to the air
 - Location of building and possible air pollutants
 - Heat gain
 - Climate, e.g. outdoor temperature or wind velocity
- Can achieve passive cooling effect
 - Technologies or design features used to cool buildings without power consumption

Design strategies of natural ventilation

Ventilation Strategy

• Hybrid ventilation (mixed mode ventilation)

- = Natural ventilation + Mechanical ventilation (and/or full air conditioning)
 - Use them at different time of the day or seasons of the year
 - Usually have a control system to switch between natural and mechanical modes
 - Combine the advantages of both to satisfy the actual ventilation needs and minimise energy consumption

(See also: <u>http://www.build.com.au/mixed-mode-hybrid-ventilation</u>)

Ventilation Strategy

- Three types of mixed mode/hybrid ventilation:
 - <u>Concurrent</u> (Same space, same time)
 - Air-conditioning system and operable windows operate in the same space and at the same time
 - <u>Change-over</u> (Same space, different times)
 - "Changes-over" between natural ventilation and airconditioning on a seasonal or even daily basis, such as by using the building automation system
 - <u>Zoned</u> (Different spaces, same time)
 - Different zones within the building have different conditioning strategies

(See also: <u>http://www.designbuilder.co.uk/helpv2/Content/Mixed_mode.htm</u>)

Ventilation Strategy

Design assessment techniques

1. Full scale mock-up

- For a representative section of the building
- It is placed in a large environmental chamber that can simulate external conditions (e.g. solar, wind)
- Evaluate HVAC system and the control system
- 2. <u>Analogue modelling</u>
 - Air movement in convective flow (natural ventilation) may be modelled in a water tank, using salt solutions
 - For a scale model of a section of the building

Ventilation Strategy

- Design assessment techniques (cont'd)
 - 3. <u>Mathematical modelling</u>
 - Building thermal simulation and computational fluid dynamics (CFD)
 - Modelling of energy use and air movement
 - 4. Emulation
 - An emulator consists of a simulation of a building and its HVAC system is connected to a real BMS
 - Can be used for evaluating BMS performance, training BMS operators, assisting in the development of new control algorithms, fine tuning the control parameters

Displacement Ventilation

• **Displacement flow**

- Cold supply air at a velocity nearly equal to the required velocity and displace the original air with piston-like airflow w/o mixing
- If properly designed, it can give:
 - Better IAQ in occupied zone
 - Higher space diffusion effectiveness
 - Low turbulence intensities & fewer draft problems
- Drawbacks:
 - Require greater supply volume flow rate
 - Higher construction cost

Displacement flow characteristics

(Source: http://www.price-hvac.com)

Displacement ventilation system

Displacement Ventilation

- Airflow patterns
 - Because of low discharge velocity, air motion is influenced to a large degree by convection flows
 - Convection flows (or thermal plumes) are created by heat sources, e.g. people, equipment, warm windows
 - Cold sinks (e.g. cold windows) may create flows down
- Airflow penetration
 - Supply air spread across the floor in a thin layer, filling the entire space
 - Flow around & beyond obstructions

Displacement Ventilation

- Temperature distribution
 - Temperature gradient between the floor & ceiling
 - Also known as "Stratification"
 - Affected by factors e.g. supply air volume, room cooling load, location & type of heat source, height of the space
 - Controlling stratification is critical to maintain thermal comfort
- If heating is needed, may use radiator to offset cold downdrafts near the windows

Figure 14 - Heat Source Location

Displacement Ventilation

- Stratified displacement flow
 - First introduced in Scandinavian countries
 - Low-level supply outlet
 - Above heat & contaminated sources
 - Heated air rises upward due to buoyancy effect
 - Supply air is entrained into the upward convective flow
 - Stationary level: upward flow = supply flow
 - Two-zone stratified model: upper zone & lower zone

Stratified displacement flow in a typical room

Displacement ventilation design

Displacement Ventilation

• Characteristics of stratified displacement flow

- Cold air supply of usually 100% outdoor air
- Air must be supplied at low velocity (< 0.3 m/s) & at a height less than 0.54 m above floor
- Cold air supplied at 2.8 to 5 °C lower than occupied zone
- Height of lower zone shall be higher than a seated occupant (1.4 m); all air is supply air in lower zone
- Smaller cooling load density (max. 41 W/m²)
- Return or exhaust inlets located near ceiling level

Example of analysis on displacement ventilation

<u>Question</u>: Consider a room 3 m high. What is the likely sensible heat extraction by displacement ventilation? How does this compare with conventional mixed flow air conditioning?

<u>Solution</u>: Assuming the max. temperature gradient of 3 K m⁻¹ throughout the room height, then for a room of 3 m this produces a temperature difference of 9 K between supply and extract (assuming extract is at the top of the room). Assume the maximum air change rate is 3 air change per hour, the air supply for 1 m² of floor area is 9 m³ h⁻¹ (or 2.5 L s⁻¹). This gives a sensible cooling capacity of:

 $V\rho\ Cp\ \Delta t$

where
$$V =$$
 volume flow rate (m³ s⁻¹)

 ρ = density of air (1.2 kg m⁻³)

Cp = specific heat capacity of the air (1.02 kJ kg⁻¹ K⁻¹)

 Δt = supply to extract air temperature difference (K)

So the cooling capacity is: $(2.5 / 1000) \times 1.2 \times 1020 \times 9 = 27.5 \text{ W m}^{-2}$ For mixed-flow air conditioning there can be up to 15 air changes per hour and the air supply rate for 1 m² of floor area is 45 m³ h⁻¹ (or 12.5 L s⁻¹). With a typical temperature difference of 8 K between the supply air and extract air, this gives a sensible cooling capacity of: $(12.5 / 1000) \times 1.2 \times 1020 \times 8 = 122.4 \text{ W m}^{-2}$

Chilled Ceiling

• Chilled ceiling and chilled beam (CC+CB)

- Used in Europe since mid-80s; Become popular in other countries
- Potential benefits
 - Better thermal comfort
 - Lower energy consumption
 - Smaller air flow rate
 - Low sound level
 - Green building credits

(*See also: <u>http://archtoolbox.com/materials-systems/hvac/120-chilled-beam-ceiling.html</u>)

Example of an installation with chilled beams, chilled ceiling panels and displacement ventilation

Examples of chilled ceiling panels

(Source of images: www.kuehldecken.de and www.sasint.co.uk and www.barcolair.cn)

Operating principle of chilled ceiling systems

Types of chilled beam systems

Passive chilled beams

(Source: http://archtoolbox.com/materials-systems/hvac/120-chilled-beam-ceiling.html)

Chilled Ceiling

- Chilled ceiling system: Water-based cooling
 - Ceiling-based radiant cooling panels coupled with chilled water pipes or coils (14-17 °C)
 - A combination of natural convection & radiation
 - A separate dedicated outdoor air system (DOAS) is used to dehumidify the outdoor air
- Thermal comfort
 - Supply air flow rate is lower => draft is reduced
 - Small temperature difference between room air and chilled ceiling surface

Chilled Ceiling

- Chilled ceiling: Thermal comfort (cont'd)
 - Higher indoor temperature can be used => decrease cooling loads and energy use
- Energy performance
 - Higher chilled water temp
 - => Higher chiller evaporative temp
 - => Chiller energy saving
 - Supply air flow rate is lower
 - => Fan energy saving
 - Radiation w/ mixed convection heat transfer

Example of analysis on chilled ceiling (1)

<u>Question</u>: Consider a chilled ceiling with a mean water temperature of 17 °C and a room air temperature of 27 °C. Assume a mean radiant temperature of 25 °C. Does theory confirm the output given?

Solution: Please refer to pages 400-402 of the reference book (Example 12.3).*

Numerical answers:

The total cooling output of the ceiling panels = 84 W m^{-2} The dry resultant comfort temperature = $26 \text{ }^{\circ}\text{C}$

[*Levermore, G. J., 2000. *Building Energy Management Systems: Application to Low-energy HVAC and Natural Ventilation Control*, 2nd ed., E & FN Spon, London & New York]

Example of analysis on chilled ceiling (2)

Question: A chilled ceiling system has been installed with a polypropylene pipework lattice behind the ceiling tiles. The output of the tiles is given by: $q = C(t_{mw} - t_{ai})^n$. For this system, C = 5.56, n = 1.105; $t_{\rm mw}$ is the mean water temperature in the pipes and q is the heat absorbed by the panel (W m⁻²). The flow water temperature is designed to be 14 °C and the return 17 °C with a maximum air temperature at high level of 25.5 °C. If the flow water temperature is controlled at 14 °C but the heat gain falls to half the design value, what does the room air temperature become if there is no control on the panel? Assume the heat gain is equally radiant and convective.

Solution: Please refer to pages 404-405 of the reference book (Example 12.4).*

Numerical answer:

The room air temperature = 20.09 °C

[*Levermore, G. J., 2000. *Building Energy Management Systems: Application to Low-energy HVAC and Natural Ventilation Control*, 2nd ed., E & FN Spon, London & New York]

- Three main functions of lighting:
 - Ensure the <u>safety</u> of people
 - Facilitate the performance of visual tasks
 - Aid the creation of an appropriate <u>visual</u> <u>environment</u>

• Basic principle of lighting control system

- Lighting control equipment:
 - Switches
 - Occupancy sensing
 - Scheduling (timeclocks)
 - Daylight dimming
 - Tuning
 - Preset dimming
 - Wireless controls

Wall switch Socket-style timer with motion random sensor 2:39 schedule is ideal for atfor closets home look O Wall sensor switch turns lights No-touch light off after your kids switch just leave the room needs the wave of a hand or an elbow to turn on lights O. \mathbf{c} Easy-to-install A remote wall switch and light socket \square

Remember: switch off unnecessary lights!

- Lighting controls and communications
 - Wired bus
 - Analogue (0-10 V DC)

- Control over powerline
 - Two-wire phase control
- Powerline communications
- Radio communications
 - WiFi, ZigBee, EnOcean

Lighting ballast industry has selected DALI as its standardized wired digital protocol
No generally accepted powerline communications scheme
ZigBee is leading contender for future wireless lighting and building control products

Lighting Control 1990s: Analogue (0-10 V DC bus)

Digital Lighting Control 2000s: Basic DALI (DALI = digital addressable lighting interface)

- Controllable lighting strategies: Two issues
 - Energy efficiency
 - Vacancy detection, daylight harvesting, tuning, personal controls, adaptation compensation, lumen maintenance
 - Demand response (DR)
 - Changes in energy usage by end-use customers from their normal consumption patterns in response to the change in energy price over time or incentive payments
 - Slow or real time

- New and emerging technologies
 - Intelligent/Smart luminaires
 - Multiple light sources (to support different functions), embedded sensors, controller & communications
 - Automatic, continuous calibration
 - Multi sensor input
 - Occupancy sensing integration
 - Video-based occupancy & photo controls (for both occupancy and light sensing)
 - Advanced controls algorithms (e.g. predictive)

Intelligent luminaires have the potential to integrate various sensors

Example of analysis on intelligent luminaire

<u>Question</u>: A intelligent luminaire can produce an illuminance of 800 lux on a person's desk. The desk has a reflectivity of 20%. The setpoint illuminance for the luminaire is 500 lux. The luminaire is providing a steady 300 lux on the desk when the window blind is down. The blind is then opened and daylight contributes a further 200 lux. How long does the luminaire take to adjust to this new condition with the above control schedule?

Solution: Please refer to pages 418-419 of the reference book (Example 12.5).*

Numerical answer:

The luminaire will take 28.1 seconds
